# PART II OVERALL STATEWIDE PROBLEM ANALYSIS

#### STATEWIDE SUMMARY

#### Overview

The number of persons killed on the state's highways in 1986 totalled 714, a 3.6% decrease from the 1983-1985 three-year baseline average of 741. There was a 0.2% drop in the total number of fatal collisions for 1986 compared to the average for 1983-1985. Increases for 1986 over the three-year baseline period were recorded in the categories of total collisions, injury collisions, total number of persons injured and property damage only collisions (Table 1-1).

Table 1-1

			F COLLISIONS Comparison			
		Previous 3 Year	% of Change 86 - 3 Year			
Impact	1986	1985	1984	1983	Average (83-85)	Average

Fatal Collisions Total Killed	658	656 756	687 761	635 705	659 741	-0.29
Injury Collisions	46,090	44,373	42,076	40,273	42,241	9.1
Total Injured	66,707	63,806	61,366	58,317	61,163	9.1
Property Damage Only Collisions	76,170	75,027	68,892	65,689	69,869	9.0

#### Exposure

A 9.7% increase in motor vehicle miles travelled was recorded for 1986 over the 1983-1985 baseline period. Motor vehicle registration jumped by 5.5% over baseline while the number of licensed drivers was up 3.0%. In 1986 the state's population increased over the 1983-85 average by 2.0% to a total of 4,419,700 persons (Table 1-2).

Table 1-2

		VEHICLES AF Four Year				
		Ye	ars		Previous 3 Year	% of Change

<sup>\*</sup>In Millions

<sup>\*\*</sup>Preliminary Estimate for 1986

#### Rates

The 1986 motor vehicle traffic death rate dropped to an all time low of 1.96 deaths per 100 million vehicle miles of travel, down from the 2.22 rate recorded in 1985. The rate of 1.83 injuries per one million vehicle miles in 1986 was down slightly from the 1.88 rate for 1986 and down from the 1.84 rate recorded for the baseline period (Table 1-3).

Table 1-3

		DEATH AND INJ				
		Year	Previous 3 Year	% of Change		
Rates	1986	1985	1984	1983	Average (83-85)	Average
Death Rate (Deaths per 100M vehicle miles)	1.96	2.22	2.28	2.18	2.23	-12.13
Injury Rate (Injury per 1M vehicle miles)	1.83	1.88	1.84	1.81	1.84	-0.5

## Fatalities By Status

Driver continued in 1986 as the most common status of those killed as a result of motor vehicle collisions. Fatalities in this classification, however, decreased from 362 in 1985 to 353 in 1986. The 1986 figure decreased 3.5% from the average of the three previous years. The number of passengers killed decreased by a greater number in 1986 when 175 persons were killed, a decrease of 36 from the 1985 total. The 175 total was also down from the 194 average for the baseline period. The number of motorcycle drivers fatally injured in collisions decreased from 75 in 1985 to 71 the following year. Last year's total was up one from the three year baseline (Table 1-4).

Table 1-4

			ED BY STATUS Comparison			
		Year	Previous 3 Year	% of Change		
Status	1986	1985	1984	1983	Average (83-85)	Average

Motorcycle Passengers	9	7	10	5	7	22.77
TOTAL	714	756	761	705	741	-3.6

## Traffic Collisions, Deaths, Injuries, Travel And Death Rates

The 714 traffic fatalities recorded in 1986 were the second lowest in Washington's recent history. The steady decline in the number of traffic fatalities that followed the state's 1979 high point of 1,034 reached bottom at 705 in 1983 but then ascended to 761 the following year (Figure 1-1). Motor vehicle travel in 1986 increased by 7.2% over 1985 to reach an all-time high of 36,416 billion miles (figure 1-2).

The state's 1986 traffic fatality rate of 1.96 deaths per 100 million vehicle miles of travel continued below the national rate of 2.57 for the year. The state rate thus dropped to the lowest point in Washington's history, exceeding the previous low of 2.18 recorded in 1983 (Figure 1-3). Total reported motor vehicle traffic collisions and injuries increased over 1985. Total collisions were up 2.4% while the number of persons injured rose by 3.9% (Figure 1-4).

## Collisions By Type

A 5.0 % increase in multiple vehicle collisions over 1985 was recorded in 1986 (Figure 1-5). Single vehicle collisions were down 4.4% (Figure 1-6). Vehicle-pedestrian collisions increased 10.0% from 1985 (Figure 1-7). Vehicle-pedalcyclist collisions experienced a sharper increase of 13.7% in 1986. This is the second year in a row that a sharp increase in pedalcyclist collisions was recorded.

## Traffic Deaths And Death Rates By County

In 1986 fatalities ranged from a high of 164 in King County, with a death rate of 1.4 (traffic deaths per 10,000 registered vehicles) to a low of zero deaths in Columbia, San Juan and Wahkiakum Counties. Ferry County recorded the highest death rate at 11.66, computed on four fatalities, followed by Adams County, which recorded an 8.7 death rate on 12 deaths. Pend Oreille recorded an 8.2 death rate on six deaths, and Lincoln recorded a rate of 8.1 based on nine traffic deaths (Figure 1-9).

## Highways, Travel And Fatalities

The U.S. and State Numbered System (other than the Interstate System) was the most-traveled road system in the state, recording 11.518 billion miles, up from the 10,618 billion miles of 1985. The interstate system continued to have the lowest death rate of all the state systems, with a 0.66 rate recorded in 1986, down from the 0.94 rate recorded in 1985. Travel on city streets increased to 8.501 billion miles in 1986 and recorded a death rate of 1.52, up from 1.48 in 1985.

County roads were traveled 7.100 billion miles and recorded a death rate of 3.25 in 1986, a decline from the previous year's 3.33 rate. Total motor vehicle travel in the state increased from 33.980 billion miles to 36.416 billion (Table 1-5).

#### EXPLANATION OF PROBLEM ANALYSIS PROCESS

## Explanation Of Problem Analysis Process

In developing the Problem Identification section for the 1988 Highway Safety Plan (HSP), problem areas were classified into two basic types: impact problems and system support problems.

Impact problems are those whose factors contribute directly to the occurrence of collisions, fatalities and/or injuries and may be corrected through the implementation of countermeasures designed to reduce the effects of these factors.

System support problems are those deficiencies within vital traffic safety programs whose correction may not be directly reflected in a reduction in traffic collisions, injuries or fatalities.

The basis for impact and system support problem identification, analysis and selection for inclusion into the HSP was done in two ways.

- 1. Impact problem areas were based on identifying statewide experience in impact areas where information was available) outlined in the Federal safety standards. Various statewide automated and manual traffic information systems were inventoried and analyzed. The data sources included: Traffic Accident Records, Fatal Accident Reporting System, Driver's Licensing Records, Vehicle Registration Records and Highway/Roadway Information. In most instances, four years' worth of data were gathered as a baseline to serve as a point of comparison to the current year's activity level.
- 2. The second source for problem identification inclusion in the HSP resulted from analysis by and for various state and local agencies with an interest in highway safety. The Washington Traffic Safety Commission made it known that the two main emphasis areas in FY 1988 were the non-use of occupant restraint systems, and alcohol-related collisions.

## Data Analysis And Statistical Techniques

Data analysis was a key factor in the identification and selection of the traffic problem areas included in this Plan. The analyses were performed to ensure that the conclusions drawn from the data were valid and credible.

The most common data sources in the HSP were the statewide traffic collision records, which were used for identifying the specific traffic problem areas. Four continuous years (1982-1985) of collision experience were used to serve as a baseline in analyzing traffic collision data. This baseline was used to obtain a better perspective to assess the current

year's (1986) experience with traffic problem areas. The baseline also serves to negate short-term changes in collision patterns.

The development of over/under-representation ratios were the most frequently used methods of analysis. Where relevant exposure data were available, the generation of over-representation ratios allow for the comparisons of different subgroups relative to the percentage of the population they comprise. Additionally, county and city rankings were generated for different problem areas to compare geographical and political subdivisions.

# ANALYSIS OF SELECTED TRAFFIC PROBLEMS

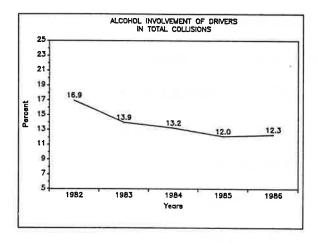

- Alcohol Involvement
- Youth Involvement
- Safety Restraint Usage
- Motorcycle Collisions
- Pedalcycles
- Pedestrians
- Heavy Trucks
- Pupil Transportation
- Contributory Driver Violations
- Vehicle Defects
- Senior Driver Involvement

## ALCOHOL INVOLVEMENT

#### Overview

In 1986, 12.3% of all drivers involved in traffic collisions had been drinking alcohol. This is a 2.5% increase from 1985 and reverses a previous four-year downward trend (Figure 2-1).

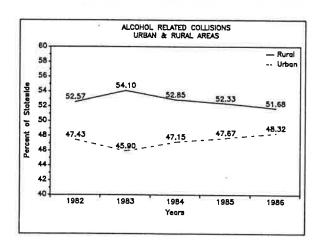

Figure 2-1

#### Location Of Alcohol-Related Collisions

In 1986 the urban-rural breakdown of alcohol-related collisions continued the trend established in 1984 with a decrease in rural areas and an increase in the urban areas compared to 1985; 51.68% of the alcohol-related collisions occurred in rural areas and 48.32% in urban areas (Figure 2-2).

Figure 2-2

The predominant type of alcohol-related vehicle collision continued to be multiple-vehicle mishaps in urban areas (Figure 2-3) with the opposite holding true in rural areas (Figure 2-4). Of the urban collisions, 66.8% involved two or more vehicles while only 36.4% were multiple vehicle collisions on rural roads.

Figure 2-3

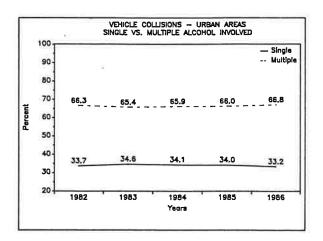

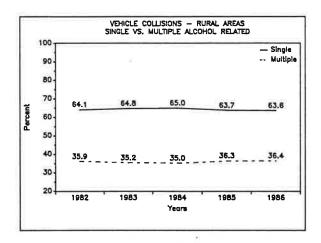

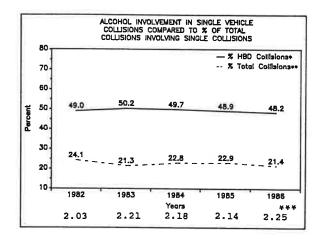

Figure 2-4

## Single Vehicle Collisions Involving Alcohol

In 1986 the percentage of all single vehicle collisions where the driver had been drinking remained relatively stable at nearly 48.2% of the total alcohol-involved collisions. By comparison the percentage of total collisions that the single vehicle collision represents was only 21.4% in 1986 (Figure 2-5). Comparing the percentage of alcohol involvement in single vehicle collisions to the percentage of total collisions the single vehicle collision represents allows for the generation of a ratio to express the over-representation of alcohol in single vehicle collisions. In 1986, this ratio reversed a decreasing trend and increased from 2.14 in 1985 to 2.25 in 1986.

- \* Had Been Drinking
- \*\* Represented By Single Vehicle

\*\*\* Ratio

Figure 2-5 shows over-involvement of single vehicle alcohol-involved collisions compared to single vehicle collisions in total collisions.

#### Drivers Involved In Fatal Collisions

In 1986, 40.4% of the drivers involved in statewide fatal collisions had been drinking intoxicants. This is an increase from the 37.5% involvement recorded in 1985 and the first increase in seven years. In rural areas, 41.3% of the drivers in fatal collisions had been drinking, down only slightly from the 1982-85 average. In urban areas, the figure was 38.3%, a 1.35% increase from baseline. (Tables 2-1, 2-1a, 2-1b)

## Alcohol Involvement By Age Group

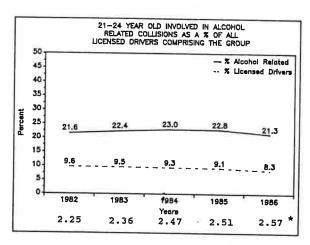

Drivers under 30 years of age continue to be over-represented in alcohol-related collisions. The 16-20 year old group comprised 7.7% of all licensed drivers in the state in 1986 but were involved in 17.1% of all alcohol-related collisions. This was an over-representation ratio of 2.22, meaning this age group was involved in slightly more than two times more alcohol-related collisions than the percentage of licensed The over-involvement drivers it represented (Figure 2-6). 2.57. This ratio for drivers aged 21-24 in 1986 was group's over-involvement ratio has climbed steadily In 1986 the 25-29 year age group was in-1982 (Figure 2-7). volved in 1.63 times more alcohol-related collisions than the percentage of licensed drivers the group represented (Figure The age group 30-54 was under-represented by a ratio of .74 last year (Figure 2-9). The remaining age group, years and older was also under-represented by a ratio of last year (Figure 2-9a).

Figure 2-9a

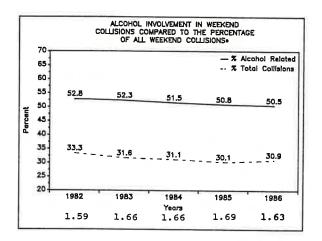

\* Ratio:

Under-involvement in alcohol-related collisions compared to % of licensed drivers in the population.

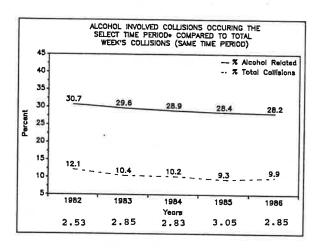

#### Weekend Alcohol Involvement

In 1986 the percentage of alcohol-related collisions occurred a rate 1.63 times greater than all weekend collisions at This was down only to Sunday midnight). 6 p.m. slightly in the over-representation ratio registered for the previous four years (Figure 2-10). In a further breakdown of weekend alcohol-related collisions comparing the percentage of alcohol-involved collisions occurring Friday and Saturday between the hours of 8 p.m. to 3 a.m. to the percentage of the total week's collisions occurring in this time frame, the three nearly alcohol-related collisions were This over-representation is down slightly over-represented. from 1985 but about equals the 1983/84 ratio (Figure 2-11).

- \*\* Over-involvement ratio

Figure 2-11

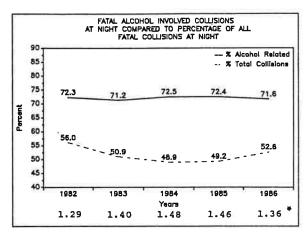

\* Friday & Saturday 8:00 p.m. to 3:00 a.m. \*\* Over-involvement ratio

# Fatal Alcohol Involved Collisions Occurring At Night

The number of all nighttime fatal collisions involving alcohol expressed as a percentage of all alcohol-related collisions dropped during 1986 compared to the previous year. This is in contrast to a slight increase in all nighttime fatal collisions. All nighttime fatal collisions in 1986 comprised 52.6% of the year's total fatal collisions while alcohol-related nighttime fatal collisions reach 71.6%. alcohol-related fatal collisions at night were over-represented when compared to all nighttime fatal collisions by a ratio of 1.36, down from the previous three-year period ratios (Figure 2-12).

Figure 2-12

\* Ratio:

Over-involvement ratio \$ nighttime alcohol fatal collisions to \$ nighttime fatal collisions.

#### Ratio of Drinking And Drunk Drivers Involved in Traffic Collisions

Slightly over forty percent (40.4%) of all drivers in fatal collisions in 1986 had been drinking prior to the collision. This is a substantial increase from the previous year of 37.5%, a record low in this category following 1980's 49.4% high (Figure 2-13). Twelve percent of the drivers involved in all investigated collisions had been drinking prior to the collision. The 1986 drinking driver total of 18,127 represents a 2.2% increase from the previous four-year average (Figure 2-14).

Figure 2-13

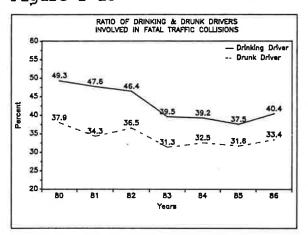

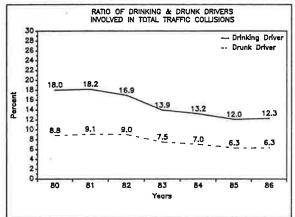

Figure 2-14

The total frequency of particular blood alcohol concentration (BAC) levels in fatal and serious injury collisions from 1982 through 1986 by age groups is presented in Table 2-2. The 16-20 and 21-24 age groups evidenced the greatest incidence of involvement for .05-.19 BAC levels. At the .15-.19 BAC range, the 20-24 age groups had the greatest frequency of occurrences. At the .20-.24 BAC levels, the 25-29 age groups had the greatest frequency of occurrences. At the .25 - .29 BAC levels, the 30-34 age group had the greatest frequency of occurrence. Overall, the 16-20, 21-24, and 25-29 age groups display the highest incidence of involvement at all BAC levels.

An analysis of roadway type by day of week on which alcohol-involved fatal and serious injury collisions occurred is given in Table 2-3. County roads accounted for 33.7% of the total weekly collisions compared to 31.2% for city streets. U.S. and state routes total 24.1% while the interstates and full-control access roads together contributed 10.0% of the weekly total of fatal and serious alcohol-involved collisions during 1986. The table also reveals that during this period of time, Saturday was the weekday with the greatest frequency of fatal and serious injury collisions involving alcohol. Sunday and Friday were the next highest days in that order.

In 1986 the number of convictions for alcohol-related traffic offenses declined for the third consecutive year. The 23,190 convictions in 1986 for DWI/Physical Control violations represented a drop of 20,645 convictions from the record high year of 1983. In 1986 the number of DWI drivers involved in investigated collisions increased to 9,335, the highest number recorded since 1982 when 10,609 drivers were involved (Figure 2-15).

Figure 2-15

\* Fiscal Year \*\* Calendar Year

Note: Convictions for physical control of vehicle while under the influence decreased from 10,520 in FY 1979 to 1,866 convictions in FY 1980. DWI convictions increased from 25,788 in FY 1979 to 27,942 in FY 1980.

Data for collision involvement by driver's age and percent of vehicle miles traveled for each age group reveal that the 19 & younger have the greatest over-representation in all reported collisions at 5.02%. The 65 & over group was the second most over-represented group. The age group with the greatest under-representation based on miles traveled was the 55-64 category. The 19 & younger group displayed the greatest over-representation in alcohol-related collisions based on miles traveled. Second in this ranking was the 20-34 year old group. The age group 55-64 recorded the greatest under-representation in alcohol-involved collisions with a 0.30 ratio (Table 2-4).

Table 2-5 presents a summary of the number of persons killed and injured, number of property damage collisions, and total investigated collisions for drivers under the influence, all drinking drivers, and non-drinking drivers. Most categories of non-drinking driver collisions showed increases over 1985. The exception is the number of persons killed and those receiving disabling injuries; these recorded modest decreases. Drivers under the influence showed increases in "Persons Killed," "Persons Injured," and "Property Damage Only Collisions." Total "DWI" Collisions recorded a 7.3% overall increase. Alcohol-related (Drivers Had Been Drinking) collisions showed a similar increase when compared to the previous year.

<sup>\*</sup>Including Drivers Under the Influence

Table 2-6 displays the number of persons killed and injured by drivers "under the influence" and "who had been drinking" by months for 1984, 1985, and 1986. The summer months typically show a higher incidence of persons killed and injured for both categories of alcohol-involved drivers. The month of November, however, recorded an exceptionally high number of persons injured in both DWI and HBD crashes in 1986.

#### YOUTH INVOLVEMENT

#### Overview

Drivers 20 years old and under comprised 7.7% of all licensed drivers in the state in 1986, yet this age group was involved in 19.0% of the total 1986 collisions. This was a collision over-representation rate 2.47 times higher than the percentage of licensed drivers comprising this group. The 21-24 age group was involved in 13.9% of the total collisions while comprising 8.3% of all licensed drivers, producing an over-representation factor of 2.17. The 25-29 year old group, comprising 12.3% of all licensed drivers, was involved in 14.7% for an over-representation of 1.20. All other age groups were under-represented when their percentages of collision involvement were compared to their percentages of total licensed drivers (Table 3-1).

# Youthful Driver Involvement in Collisions By First Harmful Event

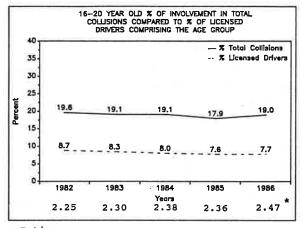

In 1986, 74.0% of those drivers age 24 years and younger who were involved in all collisions collided with other moving vehicles. This type of collision also resulted in the greatest percentage of fatal collisions (45.7%) and injury collisions (69.9%). Single vehicle collisions with fixed objects led to the second largest percentage of youthful driver involvement in total, fatal and injury collisions, at 15.5%, 26.7% and 16.9% respectively (Table 3-2).

YOUTHFUL		VOLVEMENT IN C Harmful Event		28

### Youthful Collision Involvement By Age Group

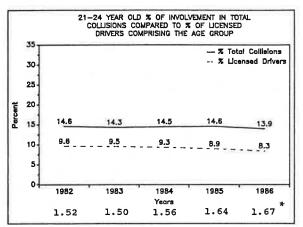

In 1986 the 16-20 year old age group was involved in 19.0% of This group's over-representation ratio of collisions. 2.47 was up from the 2.36 ratio for 1985. It is also the highest over-representation ratio for any age group 21-24 year old age group The increased 3-1).over-representation ratio from 1.64 to 1.67 (Figure The 25-29 age group posted an over-representation ratio of up from the previous year's 1.15 (Figure 3-3). age group continued to be under-represented in total collisions compared to this group's percentage of all censed drivers, as did the 55 year old and older age group (Figure 3-4 & 3-4a).

## Collision Severity By Area For Youthful Drivers

In 1986, the urban area collisions gained a full percentage point in the urban and rural mix of collisions involving youthful drivers (24 years old and younger). The urban areas recorded 58.9% of the total with the rural areas contributing 41.1% (Figure 3-5). In 1986, youthful driver injury collisions also increased in the urban area, recording 54.9% 45.1% rural (Figure 3-6). Youthful driver fatal collisions continued to be far more common in rural areas. In 1986, 69.0% of the fatal collisions involving youthful drivers occurred in rural areas. The urban area, which recorded 32.0% increased nearly 5 percentage points over 1985 of the total, and 7 percentage points over 1984 (Figure 3-7).

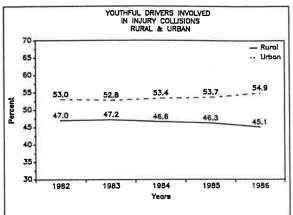

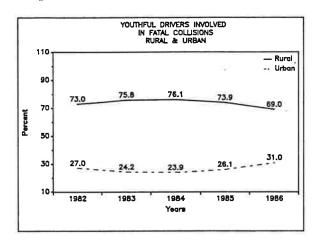

Figure 3-7

## Youthful Driver Involvement By Time

In 1986, 21.7% of all the rural fatal collisions involving youthful drivers occurred on Sunday and 18.2% of all rural reported collisions occurred on Friday (Figure 3-8). In urban areas, Saturday had the highest occurrence of fatal collisions involving youthful drivers (26.9%), but Friday recorded the greatest percentage of total collisions (18.6%) for the group (Figure 3-9).

Figure 3-8

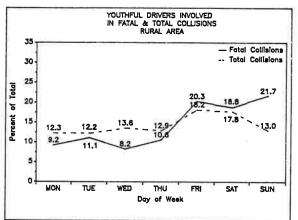

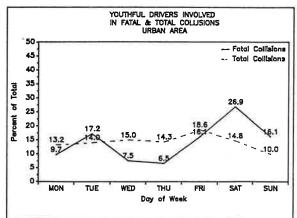

Figure 3-9

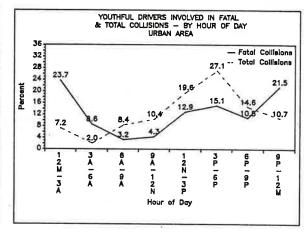

In rural areas, the greatest percentage (21.3%) of youthful driver involvement in fatal collisions in 1986 occurred from midnight to 3 a.m. The greatest percentage of total collision involvement (23.8%) for these drivers was from 3 p.m. to 6 p.m. (Figure 3-10). In the urban areas, the greatest youthful involvement by time period in fatal collisions was 23.7% in the midnight to 3 a.m. period. The 3 p.m. to 6 p.m. time period recorded 27.1% of the youthful drivers involved in total urban collisions (Figure 3-11).

#### SAFETY RESTRAINT USAGE

#### Overview

In 1986, out of a total of 188,420 occupants involved in total collisions, 102,751 were using safety restraints. This is a usage rate of 54.5% and marks the fifth consecutive year of increases in safety restraint usage since 1981 (Table 4-1).

Table 4-1

					USAGE RATE Comparison					
Status	1986	%	1985	%	1984	x	1983	%	1982	%

TOTAL	188,420	100.0%	172,277	100.0%	161,513	100.0%	151,421	100.0%	139,449	100.0%

In 1986, 102,739 persons out of a total of 188,390 collision-involved occupants were using a restraining device. Child restraints were used by 2,506 collision-involved children (Table 4-2). Looking at all restraining devices by usage and non-usage categories, it appears that with the safety restraint usage, injuries were less likely to occur and those that did occur were less severe (Appendix C, Table c-2c).

<sup>\*</sup>Excludes cases where injury severity was not stated or where restraint use was unknown.

In 1986, 59.6% of the female drivers used their restraints while 54.0% of the male drivers used their restraints in collisions. Female passengers had a usage rate of 55.0% compared to 46.7% for male passengers. The 0-5 age group had the highest restraint usage of any age group at 81.0%. The age group with the lowest usage rate was the 16-19 year olds at 44.2% usage (Table 4-3 and 4-3a).

The usage rate of safety restraints by occupation of driver ranges from a high of 85.1% for law officers to a low of 36% of for farmers and/or farm labor. Usage rates for all occupations showed substantial increases in 1987 over the rates for the preceding year (Figure 4-1).

Figure 4-1

Freeway travel (interstates) and other controlled access routes had the highest usage rate by vehicle occupants at 66.8%. Occupants of vehicles traveling on county roads had one of the lowest recorded usage rates at 50.5%. All other 72.5% roadways, which include forest service roads and recreational roads which are open to public, recorded a 41.8% usage rate. (Table 4-5).

Table 4-5

In 1986, 84.1% of the occupants were using safety restraints in "other government (federal agency) registered vehicles" involved in collisions. This is up 23.1% from the preceding year. The next highest usage rate was the 76.3% reported for state registered vehicles. Occupants of county registered and municipal registered vehicles had the lowest usage rate of occupants in all government vehicles, recording 63.8% and 66.3% respectively. (Table 4-7).

Table 4-7

Other government registered vehicles	84.1%	68.3%	58.6%	54.2%	44.4

Drivers residing within 15 miles of their collision scenes recorded the lowest seat belt usage rate in 1986. Just 55.5% in this category were using restraints. Out-of-state drivers continued to use restraints at the highest rate, 60.0%. All categories continued to record increases in restraint usage rates over previous years (Table 4-8).

Table 4-8

esided over 15 miles esiding in other state	79.1					

An examination of restraint usage by seat position in 1986 reveals that occupants in the left back and right back positions were the most frequent restraint users at 58.1% and 58.0%, respectively. These positions include the greatest usage of child restraints. Drivers were the next most frequent users at 55.9%. Seat position occupants showing the least usage of restraints were those riding in the mid-front, where 34.0% were reported using restraints (Table 4-9).

Table 4-10 presents 1986 restraint usage by occupant age seat position. The left-back and right-back for the 0-4 age group had the highest reported usage at 88.5% and 90.6%, spectively. For the 5-9 age group, the most frequent safety restraint usage also occurred in the left-back (74.5%) and right-back (74.7%) seat positions. The positions with lowest reported usage rates for the 15-20 age group were mid-front and mid-back seats--15.3% and 15.8%. The mid-back restraints were the lesser used in the 21-24 age group. driver continued to "buckle up" more than any other occupant for those ages 15 through 64. The right-front occupant was the most frequent restraint user at 65.5% in the 65 and over age category.

A more detailed breakdown of types of restraints used by jury severity is presented for 1986 in Table 4-11. Of 476 occupants killed in vehicle collisions, 414 (87.0%) were not using restraints. Of the 5,302 persons sustaining disabling injuries by collisions, 70.1% were using no restraints.

Table 4-11

Of all collision-involved drivers in 1987, those who had been drinking displayed a greater tendency not to use restraints The than those drivers who had not been drinking. latter %category revealed a restraint-usage rate of 58.8% compared to a usage rate of 26-3% for drivers under the influence and (32.3%) for drivers who had been drinking but were not under the influence (Figure 4-2).

Figure 4-2

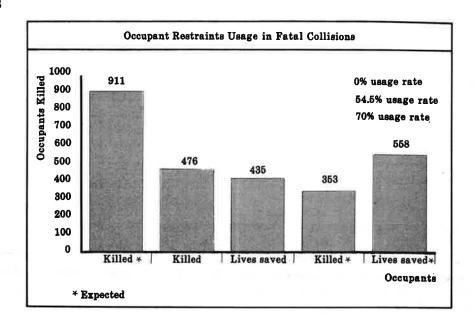

\*Drivers under the influence

\*\*Drivers had been drinking but not under influence
\*\*\*Drivers had not been drinking

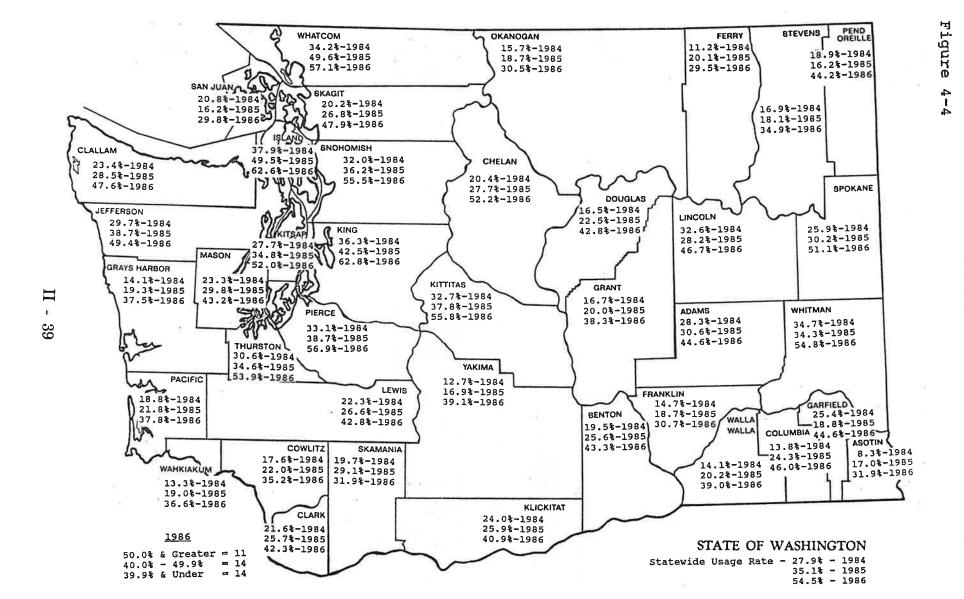

From the data obtained for restraint usage and number of fatalities in 1986, it is possible to project the number of fatalities that would have occurred under varying restraint us-(Figure 4-3). As shown in the middle block, age rates occupant restraint devices were used by 54.5% of the occupants involved in collisions. At this usage rate, there were 476 fatalities. Based on this information, it is estimated

that 435 lives were saved by restraint usage. The block to the left presents the situation that could have been expected to exist if no restraints were used. Assuming that the usage rate among vehicle occupants could be brought up to the 70% level, it is projected that there would have been 353 fatalities and 558 lives would have been saved. From these computations, it appears that the higher the usage rate, the greater the savings in lives. (See Appendix C for computation.)

Figure 4-3

A graphic depiction of restraint use by county is presented in Figure 4-4. King County, at 62.8%, had the highest usage rate of all counties in the state in 1986. Island County had the next highest usage rate at 62.6%. The two counties with the lowest usage rate were Ferry County, recording a usage rate of 29.5%, and San Juan County at 29.8%.

## MOTORCYCLE COLLISIONS

#### Overview

The 1986 motorcycle fatal collisions decreased 3.3%, when compared to the previous 4-year baseline average. ported collisions, however, recorded a 1.2% increase and injury collisions recorded a 1.7% increase over the baseline average. Registration in 1986 totaled 122,751 motorcycles, a decrease of 4.0% over the baseline period. The motorcycle collision rate of 2.86 for 1986 was up 5.4% over the baseline rate of 2.71 motorcycle collisions per every 100 registered (Table 5-1).

Table 5-1

### Motorcycle Collisions By Location

Table 5-2 displays a breakdown of motorcycle collision data by total for urban and rural areas as well as the state as whole for 1986 and 1985. In 1986 rural areas again led urban areas in the total number of fatal collisions, 45 to 35, while urban areas led rural areas in total number of collisions, 1,685 to 1,318.

Table 5-2

		COLLISIONS Year Compar							
	1986 1985								
Severity of Collision	Urban	Rural	Statewide	Urban	Rural	Statewic

Motorcyclists Injured	1,904	1,523	3,427	1,884	1,748	3,63			

A further breakdown of 1986 motorcycle collisions by road type indicates that about 55.0% of the total collisions, 53.4% of the injury collisions and 42.5% of the fatal accidents occurred on city streets. About 28.4% of the injury collisions, 27.1% of the total collisions and 27.1% of the fatal collisions happened on county roads. State routes recorded 8.9% of the injury and 8.7% of the total collisions as well as 16.3% of the fatal motorcycle collisions (Table 5-3).

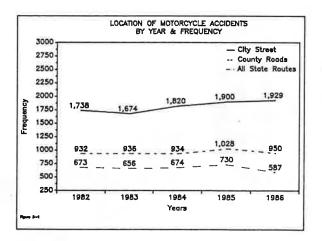

Table 5-3

			COLLISIONS ocation			2

<sup>\*</sup> Property Damage Only
\*\* Excluding city streets

Total frequency of motorcycle collisions occurring on city streets increased during 1986. This is the third year in a row where an increase occurred. Motorcycle collisions occurring on state routes reached a six-year low, recording 587 collisions. County roads recorded a decrease after a one-year increase in the number of collisions (Figure 5-1).

Figure 5-1

<sup>\*\*\*</sup> Including U.S. and State Routes in Cities

# Motorcycle Collisions By Age Group

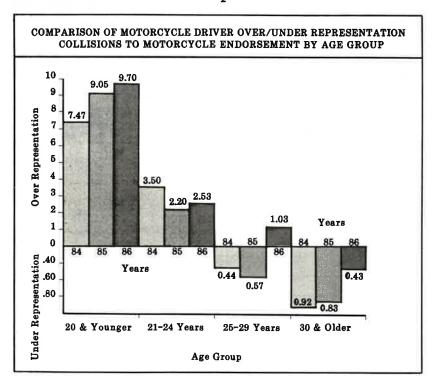

The 16-29 year old motorcycle rider continues to be over-represented in the accident population compared to the percentage of licensed motorcycle drivers comprising that age group. The 16-18 year olds were involved in 12.8% of the total collisions, but comprised less than 1% of the motorcyclists licensed to drive. From age 30 on up, motorcycle riders were under-represented (Table 5-4).

Table 5-4

		Compari	MOTOR son of Coll	CYCLE RIDE isions to		ivers		
	Fatal Col	lisions	Injury Co	Injury Collisions		Total Collisions		
Age	Number	%	Number	x	Number	×	% of Licensed Drivers	Over/Under Ratio

21-22	13	16.5%	423	14.3%	470	14.1%	2.18	6.47
23-24	10	12.7%	350	11.8%	409	12.3%	3.53	3.48
25-29	11 11	8.9%	287	9.7%	319	9.6%	5.11	1.87
30-34		13.9%   13.9%	536 357	18.1%	605	18.2%	17.63	1.03
35-39		6.3%	204	12.1%	397	11.9%	21.65	0.55
40-44	5	6.3%	124	6.9%	225	6.8%	17.18	0.39
45-54	li í	1.3%	139	4.7%	149 151	4.5%	11.49	0.39
55-64	ة اا	0.0%	59	2.0%	66	2.0%	11.64 5.97	0.39
65 & over	3	3.8%	13	0.4%	18	0.5%	2.72	0.33

Figure 5-2 shows that motorcycle riders under 29 years of age, and particularly those 20 years old and younger, were over-represented in total motorcycle accident involvement when compared to the percentages of licensed motorcycle riders comprising these age groups. The 30 year old and over age group continued to be under-represented.

Figure 5-2

### Principal Violations In Collisions By Age Group

Speed too fast for conditions was the principal cause of motorcycle collisions for all age groups in 1986, contributing to 25.3% of the year's motorcycle violations. Motorcyclists' driving while intoxicated was the second leading violation, contributing 12.1% to the violation total. Speed over the legal limit was the third most predominant violation, contributing 12.0% to the total of motorcycle driver violations. This same trend was consistent for all age groups with the following exceptions: the 24 and younger age group recorded 14.3% for speed-over limit, higher than the norm. 25-29, 30-34, and 35-44 age groups reported a higher percentage rate for driving while under the influence of alcohol than the overall population (Table 5-5).

# Motorcycle Collisions By First Harmful Event

In 1986 the most common first harmful event causing a single motorcycle collision was overturning. This cause predominated for all age groups. In multiple vehicle collisions involving motorcycles, the rear-end collision was most prevalent (14.7%). Angular collisions constituted the next most common event (14.6%) in multiple vehicle motorcycle collisions. Collisions occurring while entering or leaving a driveway contributed to 12.3% of all motorcycle collisions. (Table 5-6).

# Time Of Motorcycle Collision Occurrence

The milder weather months (June-October) of 1986 recorded the greatest percentage of motorcycle collisions. April through August recorded the most fatalities (Figure 5-3).

In comparing the frequencies of motorcycle collisions by day of week, Friday and Saturday are seen as the two days with the highest rate of occurrences. This trend has been consistent throughout the four-year baseline period and continued in 1986 as well (Figure 5-4).

Figure 5-3

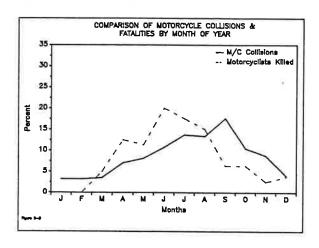

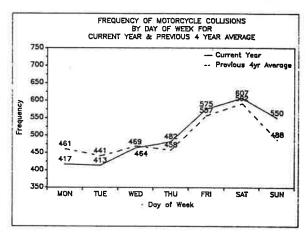

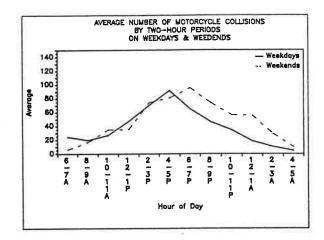

Figure 5-4

A further breakdown by hour of day when motorcycle collisions were occurring in 1986 reveals that the weekday hours from 2 p.m. to 8 p.m. constituted the most dangerous period of the day. The same 2 p.m. to 8 p.m. time frame also proved to be a dangerous time of day for weekend motorcycling (Figure 5-5).

#### Figure 5-5

#### **PEDALCYCLES**

#### Overview

In 1986 total pedalcyclist accidents increased 26.0% over the previous four-year average. The number of pedalcyclists killed increased 6.7% from the baseline period. The number of persons injured was up 25.5%. (Table 6-1).

Table 6-1

			E TRAFFIC C ve Year Com

### Rural - Urban Pedalcycle Collisions

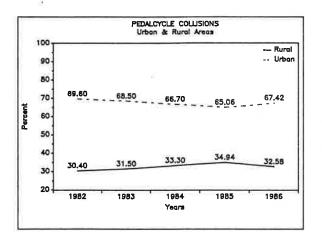

Total pedalcycle collisions in 1986 were up 25.7% in rural areas and up 26.1% in urban areas compared to a four-year baseline period. The number of persons killed in rural areas in 1986 was 6, down two from the baseline, while six persons died in urban pedalcycle collisions, up two from the average of the previous four years. Rural injuries from pedalcycle collisions were up 26.5% in 1986 over baseline while urban injuries in this regard were up 25.0% (Table 6-2).

Table 6-2

			BAN PEDALCY e Year Comp		NTS		
				Previous	% of Change

Persons Killed	6	3	3	4	4	4	71.439
Persons Injured	1,028	882	799	865	743	822	25.02

In 1986, 67.4% of the pedalcycle collisions occurred in urban areas, reversing a previous downward trend from 1982's high of 69.6%. Rural areas, however, experienced a decrease in 1986, down from the 34.9% rate in 1985, but up from the 30.4% low point in 1982 (Figure 6-1).

Figure 6-1

# Pedalcyclists Killed And Injured - By Age

In 1986, 41.7% of the pedalcyclists killed were in the 5-9 and 10-14 age brackets. These same age groups experienced 48.4% of the injuries. The number of pedalcyclists killed in 1986 increased by one from the four-year average while injuries rose by 311 (Table 6-3 and 6-4).

### Pedalcycle Fatal And Injury Collisions - By Month

The months of April through September accounted for nearly three-quarters of all injury and fatal pedalcycle accidents in 1986. This six-month period contained 72.3% of the year's total injuries and deaths (Figure 6-2).

Figure 6-2

The city of Puyallup experienced the highest pedalcycle collision rate in the state during 1986 with 87.63 collisions per 100,000 population. Olympia recorded the second highest collision rate in the state at 82.79 collisions per 100,000 population, followed by Everett with 73.99 and Kent with a 73.38 pedalcycle collision rate. (Table 6-5).

Table 6-5

#### **PEDESTRIANS**

#### Overview

The 89 pedestrians killed in 1986 were 5.3% fewer than the four-year average. The 1,752 pedestrians injured, however, were 1.9% above the four-year baseline (Table 7-1).

# Locations And Age Groups Of Pedestrian Collisions

In 1986, the number of pedestrian fatalities in rural areas was unchanged from the previous four-year average while injuries decreased 9.0%. Urban area pedestrian fatalities in 1986 declined 11.6% from baseline while injuries increased 6.0% (Table 7-2).

# Pedestrians Killed And Injured - By Age

In 1986, the overall number of pedestrians killed was identical to the 89 killed in 1985. The number of younger pedestrians ages 15 to 19 increased, however, from three in 1985 to ten in 1986 and was up two when compared to the previous four-year average. The number of older (65 & older) pedestrians injured was down one from the previous four-year average. The largest percentage increases in pedestrians injured during 1986 was in the 35-44 year age bracket and the 25-34 year age bracket, recording a 28.5% increase and 16.5% increase respectively (Tables 7-3 and 7-3a).

# Actions Of Pedestrians Killed And Injured

Thirty-four percent of the pedestrians killed or injured in the rural area of the state were struck while crossing the roadway, not at an intersection, during 1986. Another 18.2% were killed or injured while crossing at an intersection. The largest percentage of these pedestrians were in a ten-year age group of five to 14 years (Table 7-4).

## Actions Of Pedestrians Killed And Injured

In urban areas in 1986, the most frequently involved pedestrian in fatal and injury accidents fell into the 25-64 year old age group, which accounted for 40.5% of all pedestrians killed or injured in traffic accidents. The most common contributing action of this age group was "crossing, entering roadway at intersection." Thirty seven of the 62 (59.7%) of the pedestrians four years of age or younger were killed or injured while crossing the roadway between intersections. Nearly one-half (48.9%) of the pedestrians age 5-14 were also killed or injured while crossing between intersections (Table 7-5).

# Pedestrian Collisions By Day Of Week And Hour Of Day

In 1986, Friday and Thursday were the two high days for pedestrian fatalities, recording 21.3% and 16.9% deaths respectively. Friday also recorded the highest number of reported pedestrian collisions (Figure 7-1). The 9 p.m. to midnight time period evidenced the greatest percentage of fatal pedestrian collisions at 23.6%. The 3 p.m. to 6 p.m. recorded the greatest number of reported pedestrian collisions with 28.7% (Figure 7-2).

Figure 7-1

Figure 7-2

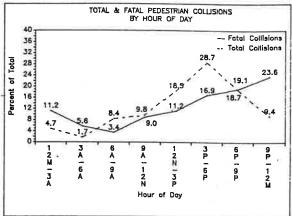

Table 7-6 below presents the 1986 number and rates for pedestrian traffic deaths, injuries, and total collisions for cities of 15,000 or more in Washington. Seattle had the greatest number of fatalities, but Auburn had the greatest rate of pedestrian fatalities at 6.68 per 100,000 population based on Seattle had the greatest number two pedestrian deaths. pedestrian collisions and pedestrian injuries. However, Bremerton had the highest rate for total pedestrian collisions (104.73 per 100,000) and second highest rate pedestrian injuries (110.71 per 100,000). Kent had the highest pedestrian injury rate with 118.80. Seattle had the second highest rate for total pedestrian collisions with 103.65 (Table 7-6).

#### **HEAVY TRUCKS**

#### Overview

In 1986 7,983 heavy trucks were involved in collisions, for a 12.3% increase over the four-year baseline. Registrations in 1986 totaled 164,000, a 10.7% increase over the four-year average. Based on this registration figure, the 1986 collision rate was 486.8 collisions per 10,000 registered trucks, an increase of 1.9% over the previous four-year average.

There were 66 heavy trucks involved in fatal collisions during 1986. This was a 12.0% decrease compared to the baseline average. The fatal collision rate of 4.0 collisions per 10,000 registered trucks was a 20.2% decrease from the baseline period (Table 8-1).

Table 8-1

<sup>\*</sup> Estimated

# Location Of Heavy Truck Collisions By Severity

In 1986, 56.9% of the heavy trucks involved in total collisions were in urban areas (Figure 8-1). In 1986 there were 16 heavy trucks involved in fatal accidents in urban areas, compared to 50 in the rural areas. These figures comprise a 24.2 - 75.8% urban/rural proportion of involvement in fatal accidents, (Figure 8-2). The 1986 heavy truck involvement in injury accidents was split, 1,098 urban to 1,159 rural. These figures are 48.6 - 51.4% urban/rural split (Figure 8-3).

Figure 8-1

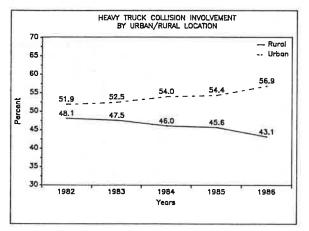

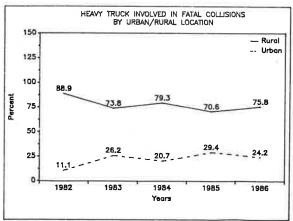

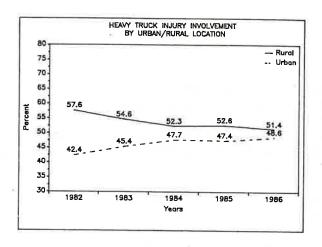

Figure 8-2

<sup>\*\*</sup>Collisions per 10,000 registered trucks

Figure 8-3

# Age Of Drivers Involved In Heavy Truck Collisions

The 39 year old and younger drivers were over-represented heavy truck collisions in 1986 compared to the percentage licensed drivers each group comprised. The 19 and under group comprised 0.3% of all licensed heavy truck operators. this group was involved in 2.8% of all heavy truck colli-3.1% of the heavy truck fatal crashes and 3.2% of the heavy truck injury collisions. The ratio for percent of collision involvement compared to percent of licensed comprised by the 19 and under age group resulted over-representation ratio of 10.78 for this group. The 20-29 year old age group was involved in 30.0% of the total 31.3% of the fatal collision and 31.4% of the collisions. This group comprised 15.1% of all drivers having classified endorsement on their licenses. Based on percent of licensed drivers and collision involvement, group was over-represented in collisions by a ratio of The 30-39 year old age group was involved in 31.3% of the total reported collisions and made up 30.5% of the drivers hava classified endorsement on their license. over-representation for this group was 1.03. The rest of the driver age groups were under-represented in total (Table 8-2).

<sup>\*</sup> Classified Endorsement is only required for operators of the larger trucks and truck combinations \*\* Percent of collision involvement to percent of licensed drivers

# Heavy Truck Collision Occurrences By Time

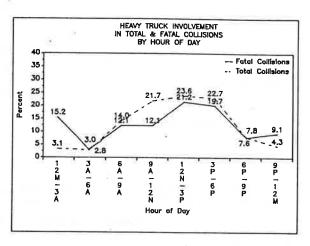

The daily frequency of heavy truck collisions in 1986 was less than those occurrences of the two previous years while following about the same frequency pattern. The weekdays had the highest frequencies of heavy truck collision involvement with Friday recording the single day high. During the weekends, there was a substantial decline in the frequency of heavy truck involvement in collisions (Figure 8-4).

In 1986, the time period from noon to 3 p.m. recorded the highest incidence of heavy truck involvement in collisions. A substantial increase in collisions commenced during the 6 a.m. to 9 a.m. time period, peaking at the noon to 3 p.m. period, remaining high during the 3 p.m. to 6 p.m. period and then taking a sharp decline (Figure 8-5).

Figure 8-4

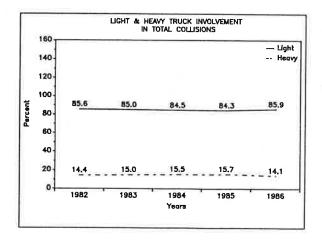

Figure 8-5

# Total Collisions - Light Trucks vs. Heavy Trucks

In 1986 there were 48,572 light trucks and 7,983 heavy trucks involved in collisions. This 85.9% - 14.1% ratio between light and heavy trucks represents a slight change from the ratios of the previous three years (Figure 8-6).

Figure 8-6

#### Collisions By First Harmful Event

During 1986 heavy trucks were involved in 5,686 collisions involving other moving motor vehicles. This figure represents 73.7% of all heavy truck collisions. Heavy trucks also were involved in 600 collisions in which the other vehicle was parked and in 792 collisions with fixed or other objects. Overturning, other non-collisions and all other collisions accounted for the remaining heavy truck-involved collisions (Table 8-3).

### PUPIL TRANSPORTATION

#### Overview

In the 1985-86 school year there were 338 reported school bus collisions in which 147 persons were injured. This represented a 24.6% increase over the previous three-year average in total school bus collisions but a 1.6% decrease in the number of persons injured. Injuries to pupils riding in the school buses totaled 29 for the 1985/86 school year, down 35.6% from the average of 45 pupils injured in the 3-year baseline period. There were 6,121 registered school buses in the 1985-86 school year. This marked a 0.2% decrease in registrations from the baseline period. School bus travel increased 8.8% during the 1985-86 school year compared to the previous three-year baseline period (Table 9-1).

In the 1985-86 school year, the school bus mileage collision rate was .51 collisions per 100,000 miles of travel (Figure 9-1). This rate was down from the 1984-85 rate of .054 but up from the 0.45 rate of the previous three-year baseline (Figure 9-1).

# CONTRIBUTORY DRIVER VIOLATIONS

#### Overview

Driving while under the influence of intoxicating liquor contributed to 31.4% of the driver violations in fatal collisions and 8.1% of all investigated collisions. Failure to yield right of way contributed to 20.8% of all investigated collisions and 5.3% of the violations in fatal collisions (Figure 10-1).

Figure 10-1

#### VEHICLE DEFECTS

#### Overview

In investigated collisions during 1986, only 5.13% of the collision-involved vehicles were found to have contributory vehicle defects. The most common defect was worn or smooth tires, a defect found in 3,129 vehicles. This represented a 4.3% increase in this category compared to the previous four-year average. Defective brakes, the second most contributory defect, was found on 2,026 collision-involved vehicles in 1986. This was an increase of 21.0% compared to the baseline (Table 10-1).

# SENIOR DRIVER INVOLVEMENT

#### Overview

Drivers 55 years old and older were involved in 25,842 reported collisions, 140 fatal collisions, and 9,560 injury collisions during 1986. This was a 12.1% increase in reported collisions, 10.9% in injury collisions but a decrease of 0.9% in fatal crashes compared to the previous four-year There were 719,784 licensed drivers 55 baseline period. years old and older in 1986, up 6.7% from the baseline pe-The fatal collision rate (total collisions per 1,000 riod. licensed drivers) of 0.19 for 1986 was down 9.1% from the baseline period (Table 11-1).

# Senior Driver Involvement In Collisions By First Harmful Event

In 1986, 86.8% of those drivers 55 years and older who involved in all reported collisions collided with other moving vehicles. This type of collision also resulted in the greatest percentage of fatal collisions (56.3%) and injury collisions (83.8%). Single vehicle collisions with a fixed object led to the second largest percentage of senior drivers involvement in total, fatal and injury collisions at 6.1%, 22.7% and 7.1% respectively. While collisions with pedestrians and bicycles comprised only 2% of the total senior driver collisions, this collision type contributed to 11.7% of the fatal crashes and 5.1% of the senior's injury collisions (Table 11-2).

SENIOR DI		EMENT IN COLLI Harmful Event					
	Total	Collisions	Fatal	Collisions	Injury Collisions

Collision with fixed/other object Overturning & other non collision	1,468 351	6.1%	29 9	22.7%	626 188	7.17	
Collisions with pedestrian & bicycles Other collisions including RR train, animal	472 221	2.0%	15 3	11.7%	452 30	5.12 0.32	
TOTAL	23,984	100.0%	128	100.0%	8,825	100.03	

# Senior Driver Collision Involvement By Age Group

Failure to yield right-of-way contributed to 49.1% of the total driver violation for drivers 75 years and older. This violation was also the leading violation for all drivers 55 years and older. This was followed by disregarding traffic control signs and signals for drivers 65 and over while speed too fast for conditions was the second leading contributing cause for drivers in the 55-59 group and the 60-64 year group (Table 11-3).

<sup>\*</sup>Investigated collisions only

1986 the 55-59 year old group was involved in 6,978 ported collisions for 3.68% of all collisions. This group made up 5.74% of the total number of drivers licensed to drive in this state. The under-representation ratio of 0.64 was down from the 0.65 ratio of the previous year and also down slightly from the previous four-year baseline average (Figure 11-1). The 60-64 age group posted under-representation ratio of 0.57, down slightly from the previous four-year baseline average (Figure 11-2). The 65-69

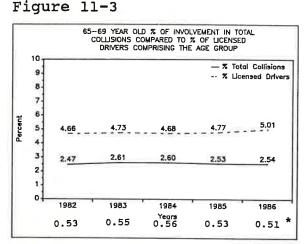

year old group recorded a 0.51 under-representation ratio, down from the .54 four-year average (Figure 11-3). The 70-74 age group recorded a 0.53 under-representation ratio, down from the .58 baseline average (Figure 11-4). The last group is the 75 years old and older group. This group had a .61 under-representation, also down from the baseline ratio of .67 (Figure 11-5).

\*Ratio: Under-representation ratio

Figure 11-4

\*Ratio: Under-representation ratio

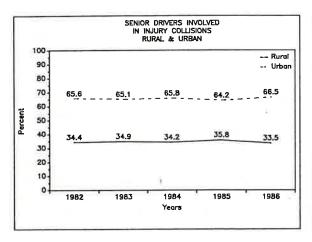

Figure 11-5

\*Ratio: Under-representation ratio In 1986, urban collisions involving senior drivers (55 years old and older) increased slightly to 66.5% while rural collisions involving senior drivers made up 33.5% of the total (Figure 11-6). In 1986, senior driver injury collisions decreased in both the rural and urban areas over 1985 (Figure 11-7). Senior driver fatal collisions continued to be more common in rural areas. In 1986, 69.3% of the fatal collisions involving senior drivers occurred in rural areas (Figure 11-8).

Figure 11-6

Figure 11-7

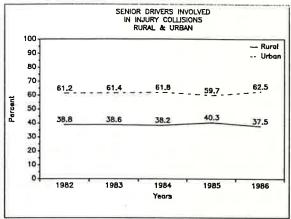

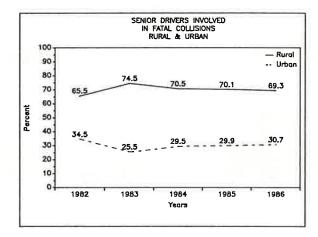

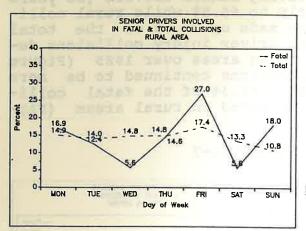

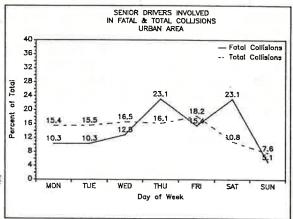

Figure 11-8

### Senior Driver Involvement By Time

In 1986, 27.0% of all rural fatal collisions involving senior drivers occurred on Friday, 18% occurred on Sunday and Monday recorded 16.9%. Friday was the high day of the week for total reported rural collisions, recording 17.4% of the senior driver collisions followed by Monday with 14.9% and Wednesday and Thursday each with 14.8% of the collisions (Figure 11-9). Thursday and Saturday were the two highest fatal accident days, each recording 23.1% of the senior driver urban area collisions. Friday recorded the greatest percentage of urban total reported collisions (18.2%) for the group (Figure 11-10).

In rural areas, the greatest percentage (30.3%) of senior driver involvement in fatal crashes in 1986 occurred from 3 p.m. to 6 p.m. The greatest percentage of total collision involvement (28.0%) for these drivers also occurred from 3 p.m. to 6 p.m. (Figure 11-11). In the urban areas, the greatest senior involvement by time period in fatal collisions was 30.8% in the 3 p.m. to 6 p.m. period. This same time frame recorded 29.3% of the total urban reported collisions of the senior drivers (Figure 11-12).
